# 1 Delta-Epsilon Proofs

## 1.1 Brief Overview

The formal definition of the limit  $\lim_{x \rightarrow c} f(x) = L$ :

**Definition:** If for any  $\epsilon > 0$ , a  $\delta > 0$  can be found such that for all  $0 < |x - c| < \delta$ , it can be proved that  $|f(x) - L| < \epsilon$ , then  $\lim_{x \rightarrow c} f(x) = L$ .

The *general steps* are as follows:

- Write: "For any  $\epsilon > 0$ , we want to pick a  $\delta > 0$  such that  $0 < |x - c| < \delta \implies |f(x) - L| < \epsilon$ "
- Start with  $|f(x) - L| < \epsilon$  to start getting it under  $\delta$  control (e.g. by expressing the LHS in terms of  $\delta$ )
- Pick an arbitrary value of  $\delta = a$  (if in doubt, choose  $a = 1$ ) and modify  $0 < |x - c| < a$  to write  $x$  in terms of  $a$ . Substitute this back into  $|f(x) - L| < \epsilon$  to fully express the LHS in terms of  $\delta$ .
- Solve for  $\delta$  in terms of  $\epsilon$  and pick  $\delta = \min\{a, f(\epsilon)\}$ .

A few *tips/tricks*:

- Apply the **Triangle Inequality**:  $|a + b| \leq |a| + |b|$ .
- Apply the identity:  $|ab| = |a||b|$ .
- Apply the inequality:  $\frac{1}{x} > \frac{1}{x + a}$  for  $x > 0$  given  $a > 0$ .
- Remember that  $0 < |x - c| < \delta \implies c - \delta < x < c + \delta$ .

**Example 1:** (2019 Midterm, Modified) Prove  $\lim_{x \rightarrow 2} \frac{3x + 1}{(x + 1)^2} = 1$ .

For any  $\epsilon > 0$ , we want to pick a  $\delta > 0$  such that  $0 < |x - 2| < \delta \implies \left| \frac{3x + 1}{(x + 1)^2} - 1 \right| < \epsilon$ . We can start with:

$$\left| \frac{3x + 1}{(x + 1)^2} - 1 \right| < \epsilon \implies \left| \frac{3x + 1 - (x^2 + 2x + 1)}{(x + 1)^2} \right| \tag{1}$$

$$\implies \left| \frac{x - x^2}{(x + 1)^2} \right| < \epsilon \tag{2}$$

$$\implies \left| \frac{x(1 - x)}{(x + 1)^2} \right| < \epsilon \tag{3}$$

$$\implies \left| \frac{x}{(x + 1)^2} \right| |x - 1| < \epsilon \tag{4}$$

$$\implies \left| \frac{x}{(x + 1)^2} \right| |(x - 1 - 1) + (1)| < \epsilon \tag{5}$$

$$\implies \left| \frac{x}{(x + 1)^2} \right| (|x - 2| + |1|) < \epsilon \tag{6}$$

$$\implies \left| \frac{x}{(x + 1)^2} \right| (\delta + 1) < \epsilon \tag{7}$$

$$\tag{8}$$

We can set  $\delta = 1$ . If this is the case then:

$$0 < |x - 2| < 1 \implies 1 < x < 3 \iff 2 < x + 1 < 4 \tag{9}$$

We can bound the denominator  $|(x + 1)^2|$  by its lower bound  $2^2 = 4$  and the numerator  $|x|$  by its upper bound of 3, which we can substitute back in to get:

$$\left| \frac{x}{(x + 1)^2} \right| (\delta + 1) < \frac{3}{4}(\delta + 1) \leq \epsilon \implies \delta \leq \frac{4}{3}\epsilon - 1 \quad (10)$$

Thus, we can pick:

$$\delta = \min\left\{1, \frac{4}{3}\epsilon - 1\right\} \quad (11)$$

and we are done. Note that we could also have applied the identity  $\frac{1}{x} > \frac{1}{x + a}$  to bound the denominator by  $1^2$  instead.

## 1.2 Special Limits

For right handed limit, we have:

**Definition:** If for every  $\epsilon > 0$ , a  $\delta > 0$  can be found such that  $c < x < c + \delta \implies |f(x) - L| < \epsilon$ , then  $\lim_{x \rightarrow c^+} = L$ .

For left handed limits:

**Definition:** If for every  $\epsilon > 0$ , a  $\delta > 0$  can be found such that  $c - \delta < x < c \implies |f(x) - L| < \epsilon$ , then  $\lim_{x \rightarrow c^-} = L$ .

For infinite limits:

**Definition:** If for every  $M > 0$ , a  $\delta > 0$  can be found such that  $0 < |x - c| < \delta \implies f(x) > M$ , then  $\lim_{x \rightarrow c} = \infty$ .

Here's an example using both:

**Example 2:** (2019 Quiz 2H, Modified) Prove the infinite limit  $\lim_{x \rightarrow 2^+} \frac{x^{3/2}}{(x - 2)^2} = \infty$ .

For any  $M > 0$ , we want to pick a  $\delta > 0$  such that  $2 < x < 2 + \delta \implies \frac{x^{3/2}}{(x - 2)^2} > M$ . We can immediately start putting  $\frac{x^{3/2}}{(x - 2)^2} > M$  under  $\delta$  control by minimizing the numerator and maximizing the denominator:

$$\frac{x^{3/2}}{(x - 2)^2} > \frac{2^{3/2}}{(2 + \delta - 2)^2} \geq M \quad (12)$$

$$\implies \frac{2^{3/2}}{\delta^2} \geq M \quad (13)$$

$$\implies \frac{\delta^2}{2^{3/2}} \leq \frac{1}{M} \quad (14)$$

$$\implies \delta \leq \frac{2^{3/4}}{\sqrt{M}} \quad (15)$$

For horizontal asymptotes as  $x \rightarrow \infty$ :

**Theorem:** If for every  $\epsilon > 0$ , a  $A > 0$  can be found such that  $x > A \implies |f(x) - L| < \epsilon$ , then  $\lim_{x \rightarrow \infty} = L$ .

**Example 3:** (Lecture 15, Assigned) Prove the limit  $\lim_{x \rightarrow \infty} \frac{1}{x^r} = 0$  where  $r > 0$ .

For any  $\epsilon > 0$ , we want to pick a  $A > 0$  such that  $x > A \implies \left| \frac{1}{x^r} \right| < \epsilon$ . We can place the LHS of  $\left| \frac{1}{x^r} \right| < \epsilon$  straight away by minimizing the denominator by selecting the lower bound of  $x$ , which is  $A$  to get:

$$\frac{1}{x^r} < \frac{1}{A^r} \leq \epsilon \implies A \geq \epsilon^{1/r} \quad (16)$$

so choosing  $A = \epsilon^{1/r}$  will always work.

## 2 Limit Theorems

Here are the limit theorems covered in class. Given  $\lim_{x \rightarrow c} f(x) = L$  and  $\lim_{x \rightarrow c} g(x) = M$  are both well defined, then:

- **Constant Limit Theorem:**  $\lim_{x \rightarrow c} A = A$
- **Additivity Limit Theorem:**  $\lim_{x \rightarrow c} [f(x) + g(x)] = L + M$
- **Product Limit Theorem:**  $\lim_{x \rightarrow c} [f(x)g(x)] = LM$
- **Polynomial Limit Theorem:**  $\lim_{x \rightarrow c} P(x) = P(c)$  if  $P(x)$  is a polynomial.
- **Rational Function Limit Theorem:**  $\lim_{x \rightarrow c} \frac{f(x)}{g(x)} = \frac{L}{M}$
- **Root Limit Theorem:**  $\lim_{x \rightarrow c} f(x)^{1/n} = L^{1/n}$
- **Sandwich Limit Theorem:** If  $\lim_{x \rightarrow c} f(x) = \lim_{x \rightarrow c} h(x) = L$  and  $f(x) \leq g(x) \leq h(x)$  near  $c$  but not necessarily at  $c$ , then  $\lim_{x \rightarrow c} g(x) = L$ .

To help with trigonometry problems, here are a few properties you should know (and understand how to derive):

- $\lim_{x \rightarrow 0} \frac{\sin x}{x} = 1$
- $\sin x \leq x \leq \tan x$  for  $x \geq 0$ . Since all these functions are odd, the inequality works in reverse for  $x < 0$ .
- $\sqrt{1 - x^2} \leq \cos x \leq 1$

*Tip:* When solving difficult trigonometry limits, try to break it up into  $\sin x/x$  terms. If not possible, try to either bound the limit using the sandwich limit theorem, or bash through applying trig identities.

## 3 Continuity Theorems

Here are the definitions for continuity at different points:

- **Continuity at a point:**  $f(x)$  is continuous at  $c$  if  $\lim_{x \rightarrow c} f(x) = f(c)$
- **Continuity on the right:**  $f(x)$  is continuous on the right of  $c$  if  $\lim_{x \rightarrow c^+} f(x) = f(c)$ .
- **Continuity on the left:**  $f(x)$  is continuous on the left of  $c$  if  $\lim_{x \rightarrow c^-} f(x) = f(c)$ .
- **Continuity on open interval:**  $f(x)$  is continuous on  $(a, b)$  iff  $f(x)$  is continuous at all  $x \in (a, b)$ .
- **Continuity on closed interval:**  $f(x)$  is continuous on  $[a, b]$  iff  $f(x)$  is continuous at all  $x \in (a, b)$  and  $f(x)$  is continuous

from the right of  $a$  and from the left of  $b$ .

There are also a few continuity theorems discussed in class:

- Given  $f, g$ , is continuous at  $a$ , then  $f(x) + g(x)$  is continuous at  $a$ .
- If  $g(x)$  is continuous at  $a$  and  $f(x)$  is continuous at  $g(a)$ , then  $f(g(x))$  is continuous at  $a$ .

## 4 Derivative Theorems

The derivative  $f'(x)$  is defined as:

$$f'(x) \equiv \lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h} \quad (17)$$

where  $h$  is a dummy variable. A few definitions:

- **Differentiability at a point:** If  $f'(a)$  exists, we say that  $f(x)$  is differentiable at  $a$ .
- **Differentiability of function:** If  $f'(x)$  is differentiable at all  $x \in \text{domain of } f(x)$ , then  $f(x)$  is a differentiable function.
- **Differentiability on open interval:**  $f(x)$  is differentiable on  $(a, b)$  if  $f'(x)$  is defined for all  $x \in (a, b)$
- **Differentiability on closed interval:**  $f(x)$  is differentiable on  $[a, b]$  if  $f'(x)$  is defined for all  $x \in (a, b)$  and the right hand derivative at  $a$  exists and the left hand derivative at  $b$  exists.
- **Relation to Continuity:** Given  $f(x)$  is differentiable at  $a$ , then  $f(x)$  is continuous at  $a$ .

When evaluating derivatives, there are a few theorems that we've learned. The following only apply if the derivatives of each function exists.

- **Constant DT:** If  $f(x) = C$ , then  $f'(x) = 0$ .
- **Additivity DT:**  $(f + g)' = f' + g'$
- **Product DT:**  $(fg)' = f'g + fg'$
- **Power DT:** If  $f(x) = Cx^n$ , then  $f'(x) = nCx^{n-1}$ .
- **Poly DT:** If  $P(x) = a_nx^n + a_{n-1}x^{n-1} + \dots + a_1x^1 + a_0$ , then  $P'(x) = na_nx^{n-1} + (n-1)a_{n-1}x^{n-2} + \dots + a_1$ .
- **Reciprocal DT:**  $\left(\frac{1}{f}\right)' = \frac{-f'}{f^2}$
- **Quotient DT:**  $(f/g)' = \frac{f'g - fg'}{g^2}$ .
- **Chain DT:**  $\frac{d}{dx}f(g(x)) = g'(x)f'(g(x)) \iff \frac{df}{dx} = \frac{df}{dg} \frac{dg}{dx}$ .

## 5 Features of a Graph

We can look at extrema points with derivatives:

- **Absolute Max:**  $f(x)$  has an absolute maximum at  $c$  if  $f(c) \geq f(x)$  for all  $x \in \text{domain of } f(x)$ .
- **Absolute Max in closed interval:**  $f(x)$  has an absolute max on  $[a, b]$  if  $f(c) \geq f(x)$  for all  $x \in [a, b]$ .
- **Local Max:**  $f(x)$  has a local max at  $c$  if  $f(c) \geq f(x)$  for some open interval containing  $c$ .

Here are a few important theorems:

**Theorem: Intermediate Value Theorem:** Given that  $f(x)$  is continuous on  $[a, b]$  and  $C$  is some number such that  $f(a) < G(a) < f(b)$ , there exists some  $C$  in  $[a, b]$  such that  $f(C) = G$ .

**Theorem: Extreme Value Theorem:** Given  $f(x)$  is continuous on  $[a, b]$ , then  $f(x)$  has an absolute maximum  $f(c)$  and an absolute minimum  $f(d)$  for some  $c, d \in [a, b]$ .

**Theorem: Rolle's Theorem:** Given that  $f$  is continuous on  $[a, b]$  and  $f$  is differentiable on  $(a, b)$  and  $f(a) = f(b)$ , then there exists some  $c \in (a, b)$  such that  $f'(c) = 0$ . Note that there may be more than one  $c$ .

**Theorem: Mean Value Theorem:** Given that  $f(x)$  is continuous on  $[a, b]$  and  $f(x)$  is differentiable on  $(a, b)$ , then there exists some  $c \in (a, b)$  such that  $f'(c) = \frac{f(b) - f(a)}{b - a}$ .

## 5.1 Estimation

We can approximate a function  $f(x + \Delta x)$  as:  $f(x + \Delta x) \approx f(x) + f'(x)\Delta x$ . For example, this allows us to estimate something like  $29^{1/3}$  as  $27^{1/3} + \frac{d}{dx}x^{1/3} \Big|_{x=27} \cdot 2$ .

An approximation by itself is useless without a bound. We can create lower and upper bounds by applying the MVT between  $[x, x + \Delta x]$  and/or between  $[x + \Delta x, x_1]$  and finding the minimum and maximum values for  $f'(x)$ .

## 5.2 Curve Sketching Prelims

We can use Fermat's theorem to determine critical points:

**Definition:**  $c$  is a critical point of  $f(x)$  if  $f'(c) = 0$  or  $f'(c)$  DNE.

Here are some key features that might be seen on a graph:

- **Concavity:** If the graph of  $y = f(x)$  lies above all its tangents in  $I$ , then  $f(x)$  is concave up in  $I$ . If it lies below, then it is concave down.
- **Cusp:** A point  $c$  is a cusp if  $f(x)$  is continuous at  $x = c$  but  $\lim_{x \rightarrow c^-} f'(x) = \pm\infty$  and  $\lim_{x \rightarrow c^+} f'(x) = \mp\infty$ .
- **Vertical Tangent:** A vertical tangent occurs when  $\lim_{x \rightarrow c} |f'(x)| = \infty$  and  $f(x)$  is continuous at  $c$ .
- **Slant Asymptote:** If  $\lim_{x \rightarrow \infty} [f(x) - (mx + b)] = 0$ , then  $y = mx + b$  is a slant asymptote to  $f(x)$  at  $+\infty$ .
- **Inflection point:** A point of inflection is at  $c$  if  $f(x)$  is continuous at  $c$  and the sign of concavity changes at  $c$ .

A function is increasing on an interval  $I$  if  $f(x_1) < f(x_2)$  for all  $x_1 < x_2$  in  $I$ . Although we can use this definition to find local max/mins, there are a few cutie (QT/quick test) ways to do so:

- **QT1: Increasing/Decreasing Test.** If  $f$  is differentiable on the interval  $I$ , we show that if  $f' > 0$ ,  $f$  is increasing. If  $f' < 0$ ,  $f$  is decreasing. If  $f' = 0$ ,  $f$  is constant.
- **QT2: First Derivative Test** Given that  $I$  contains a critical point and  $f$  is continuous at  $c_{\text{crit}}$ , and  $f$  is differentiable in  $I$  but not necessarily at  $c_{\text{crit}}$ . Then, if  $f' > 0$  to the left of  $c_{\text{crit}}$  and  $f' < 0$  to the right, then  $c_{\text{crit}}$  is a local max. If it's the opposite, we get the local minimum.
- **QT3: Concavity** Given that  $f(x)$  is twice differentiable on  $I$ , then  $f''(x)$  exists on  $I$ . As a result if  $f''(x) > 0$ ,  $f$  is concave up. If  $f'' < 0$ ,  $f$  is concave down.

- **QT4: Second Derivative Test** Given that  $f''(x)$  is continuous near  $c$  and  $f'(c) = 0$ , then if  $f''(c) > 0$ ,  $f(c)$  is a local minimum. If  $f''(c) < 0$ ,  $f(c)$  is a local maximum. If  $f''(c) = 0$ , there is no verdict.

In general, the recipe to test for local max and min is to:

- Find all  $c_{\text{crit}}$ .
- If QT4 applies, use it.
- If it doesn't, and if QT2 applies, use it.
- If QT2 doesn't apply, use the basic definition of increasing/decreasing.

### 5.3 Curve Sketching Steps

1. Determine general behaviour:
  - Find Domain / Range / Limits at  $\infty$ .
  - Determine endpoints if they exist.
  - Find vertical, horizontal, slant asymptotes if they exist:
2. Determine  $x$  and  $y$  intercepts.
3. Establish if  $f(x)$  is symmetrical, even, odd, and/or periodic.
4. Find  $f'(x)$  and use this to:
  - Find all critical points and  $f(c_{\text{crit}})$ .
  - Find when  $f(x)$  is increasing/decreasing.
  - Apply QT2.
  - Find vertical tangents / cusps if they exist.
5. Find  $f''(x)$  and use it to:
  - Find when  $f(x)$  is concave up/down.
  - Find points of inflection if they exist.
  - Optional: Use QT4 to confirm local max/min
6. Determine the absolute maximum and min by choosing the largest and smallest values of  $f$ , if they exist.
